

Development of Switchgrass as a Bioenergy Crop

Michael Casler

USDA-ARS

Dairy Forage Research Center

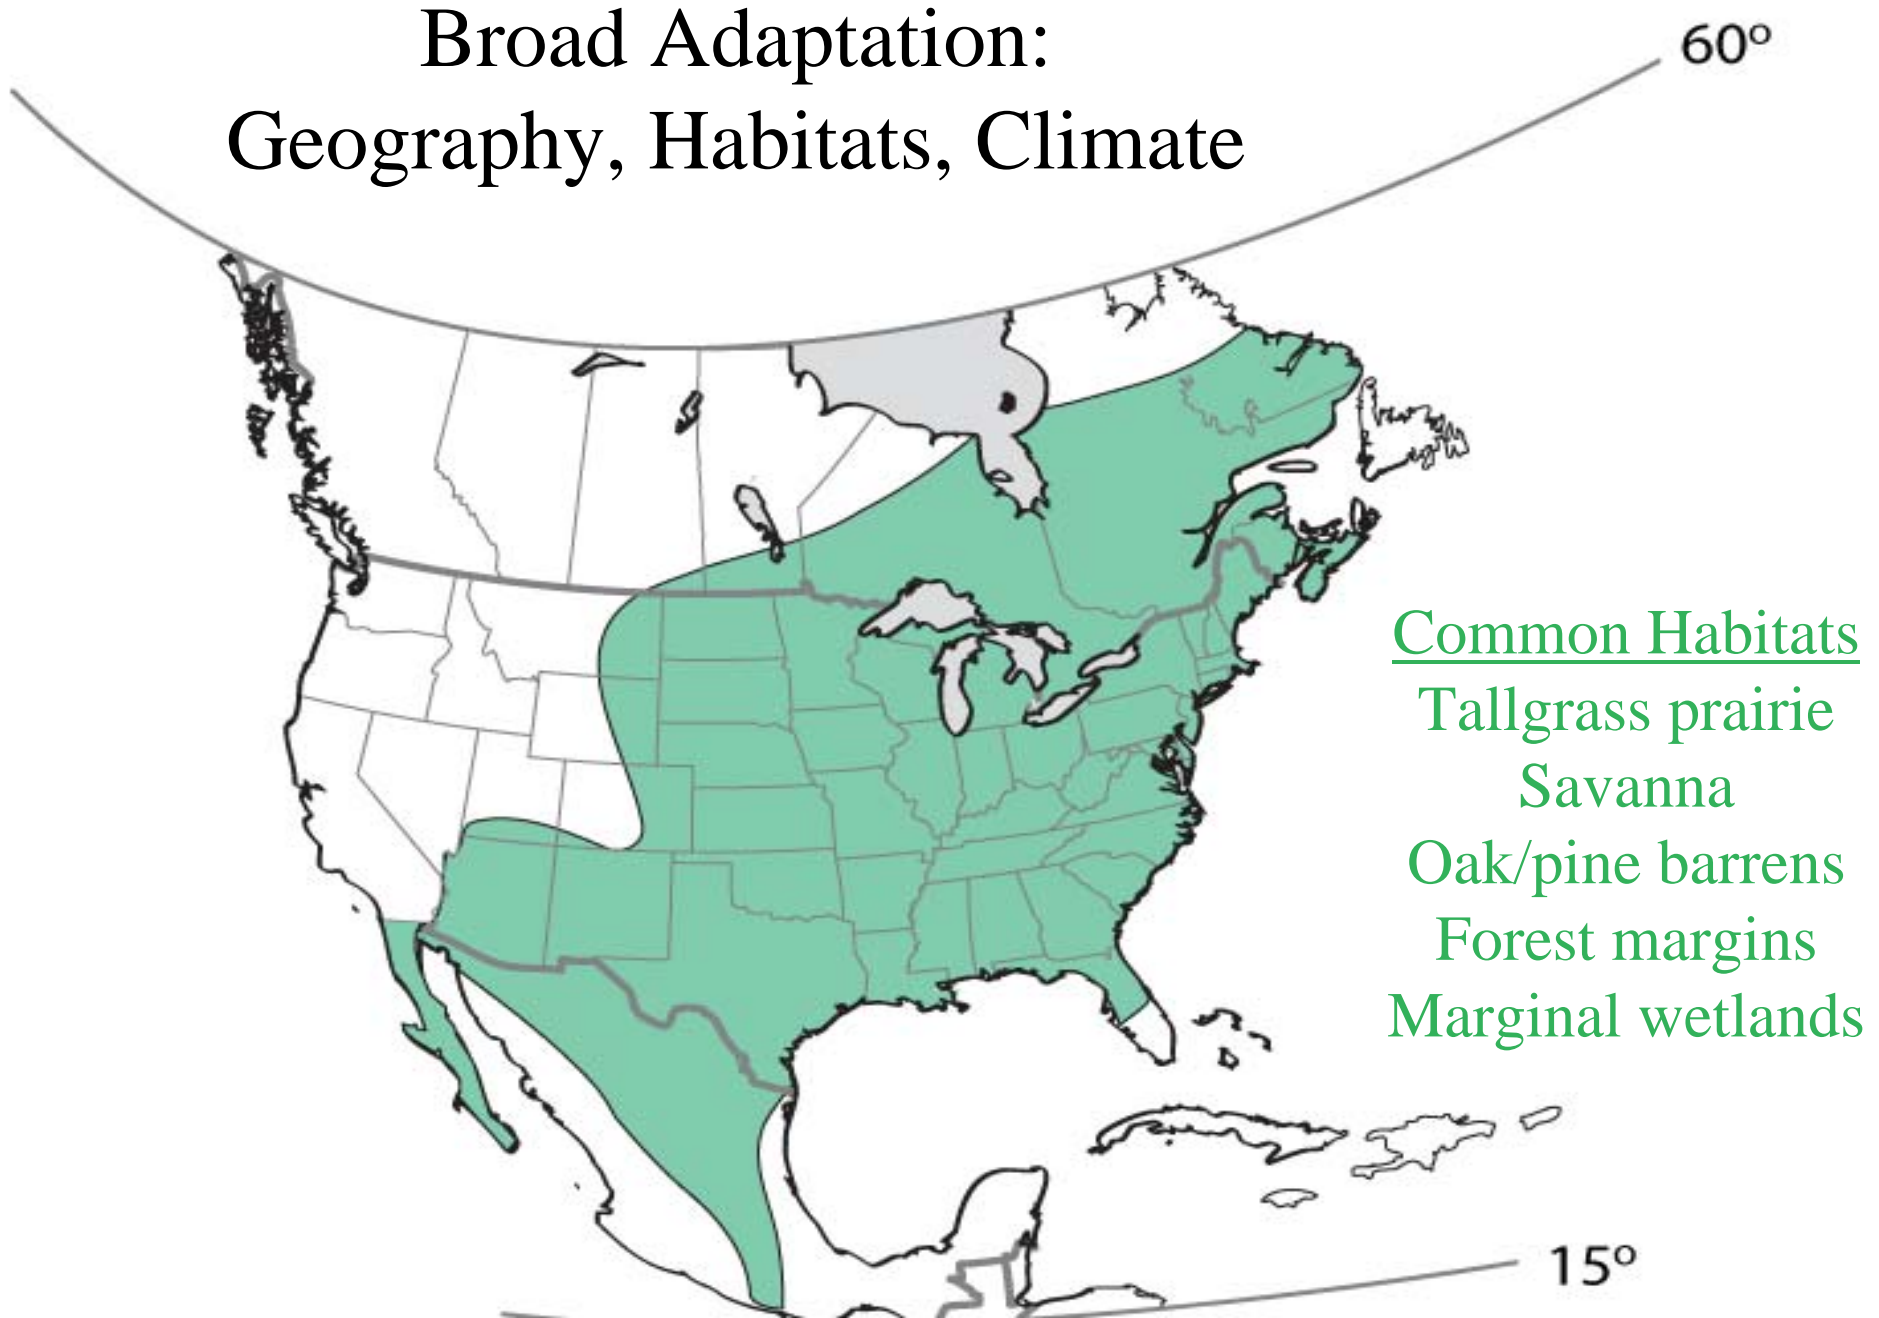

Madison, WI

U.S. Dept. of Energy, 1992

- “... to identify the best varieties and management practices to optimize productivity, while developing an understanding of the basis for long-term improvement through breeding and sustainable production in conventional ecosystems.”
- Two model species
 - Switchgrass, *Panicum virgatum* (herbaceous)
 - Poplar, *Populus* (woody)

Broad Adaptation: Geography, Habitats, Climate

Native plant with broad public and commercial appeal.

Multifunctional plant:
High biomass yields
Livestock grazing
Soil conservation
Prairie restoration

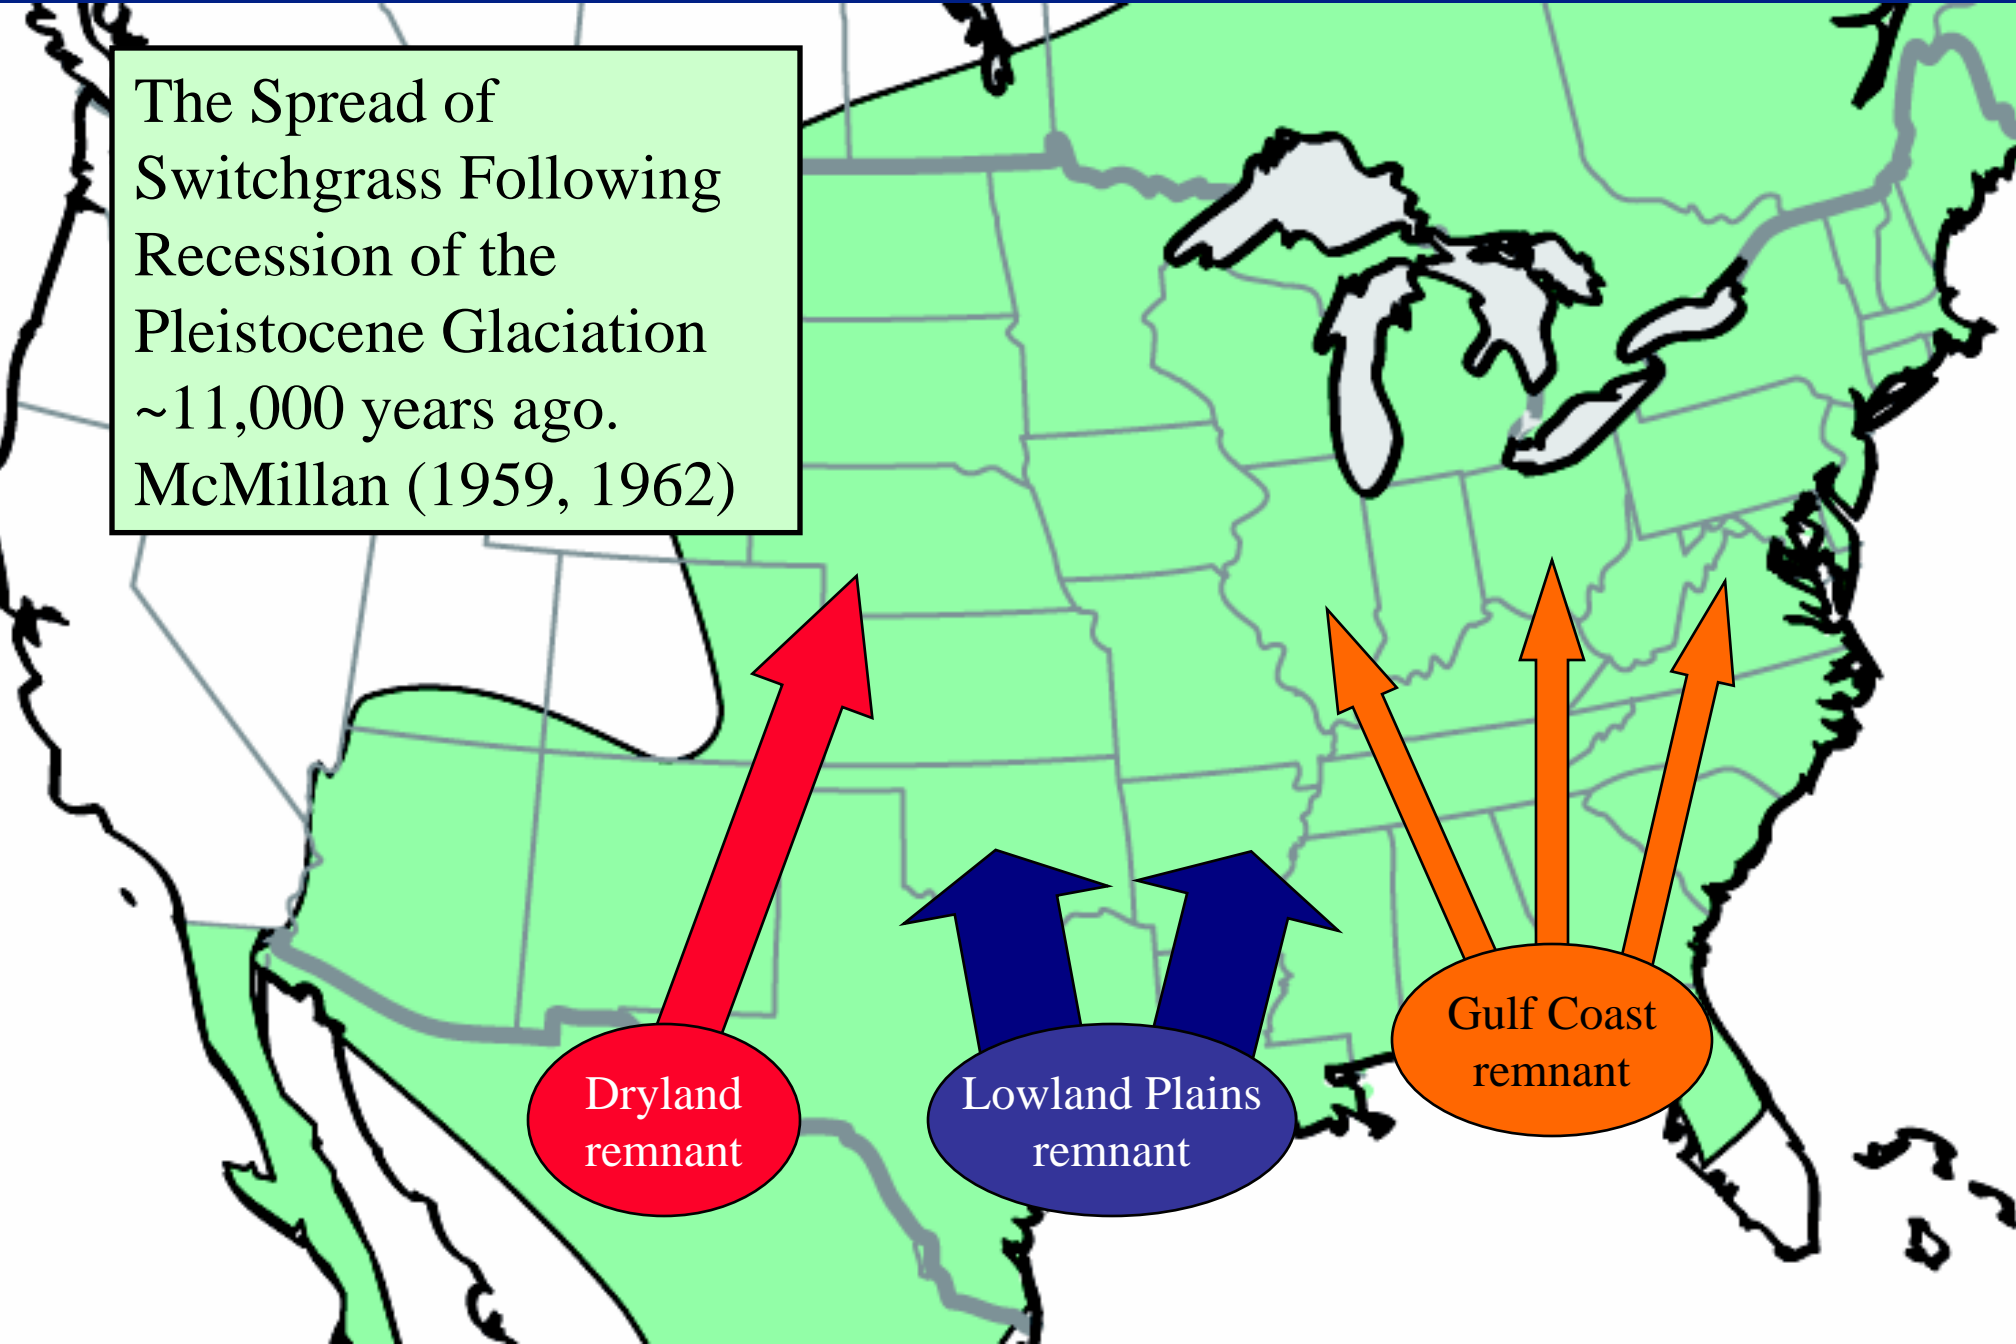

The Spread of
Switchgrass Following
Recession of the
Pleistocene Glaciation

Switchgrass Genetics

- Upland cytotype
 - Found from Texas to Canada
 - Reported chromosome numbers from $2n=2x=18$ (diploid) to $2n=12x=108$; $2n=4x=36$ and $2n=8x=72$ are most common. *Is this really true?*
- Lowland cytotype
 - Typically found from Mexico to Nebraska.
 - Chromosome number: $2n=4x=36$ (no known variants)
- Disomic (diploid) inheritance (*most likely*)

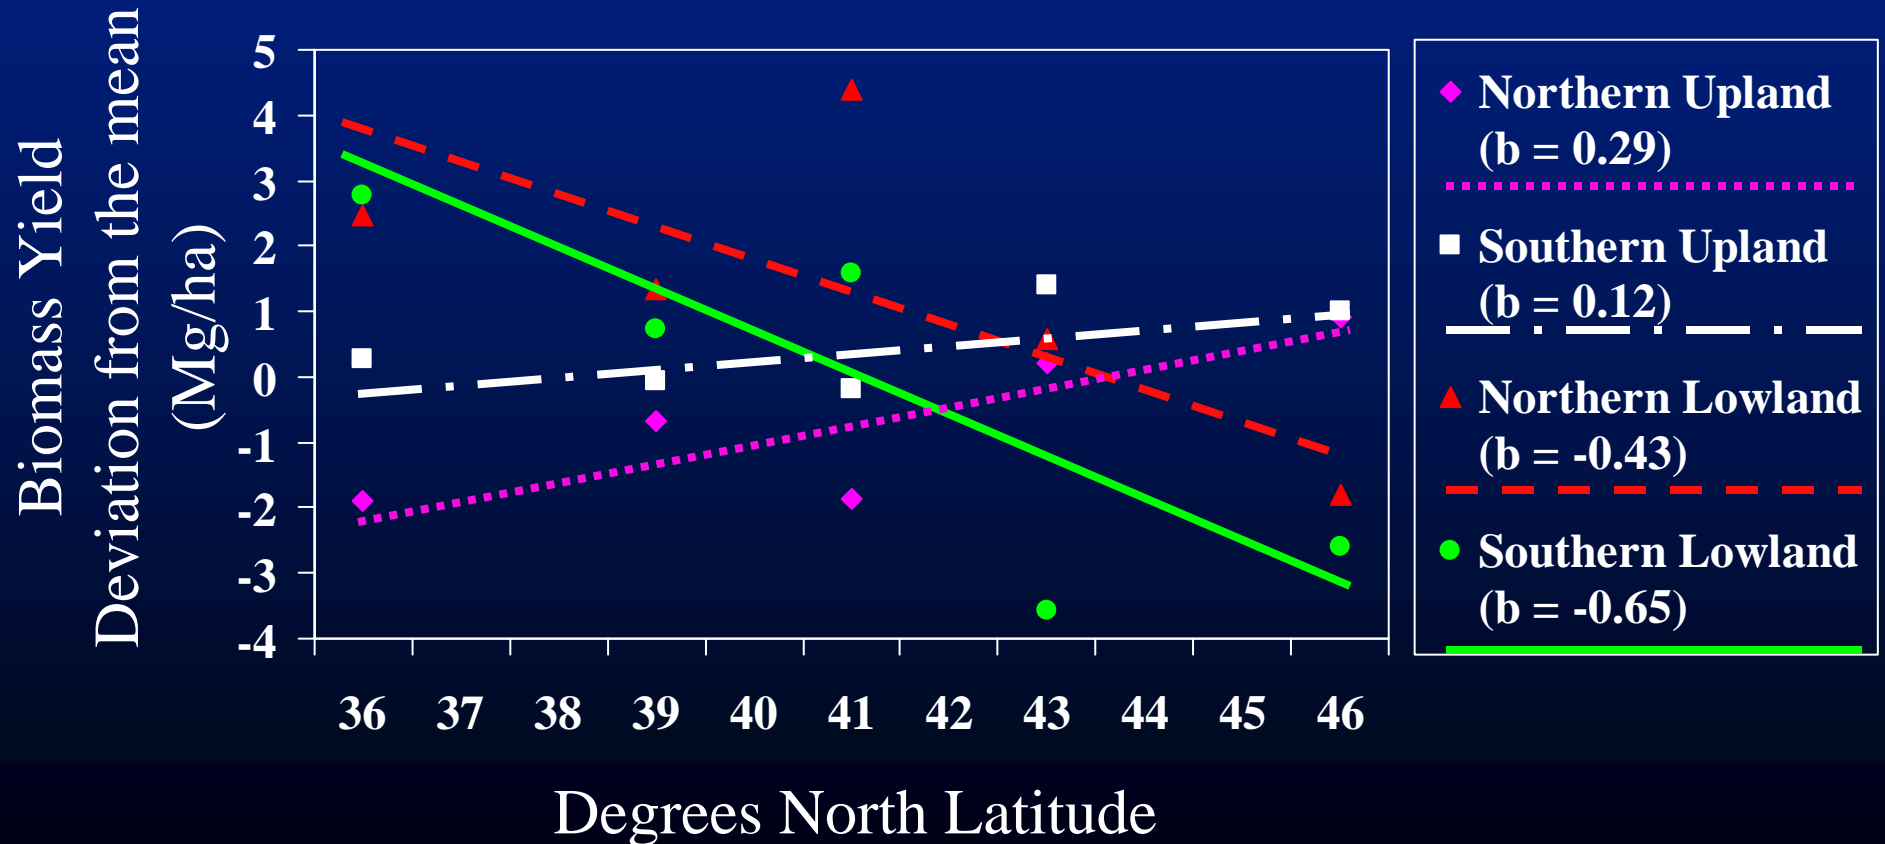

Lowland vs. Upland Cytotypes

- Lowland cytotypes...
 - Greater plant height and biomass yield.
 - Fewer tillers, greater tiller diameter, more phytomers.
 - Lower cold/freezing tolerance.
 - Greater heat tolerance.
 - Up to 2-3 weeks later in heading, anthesis, mature seed.
 - Adapted to longer growing season with reduced photoperiod.
- Moving southern populations north provides a “quick fix” to boost biomass yields, *provided that they survive*.

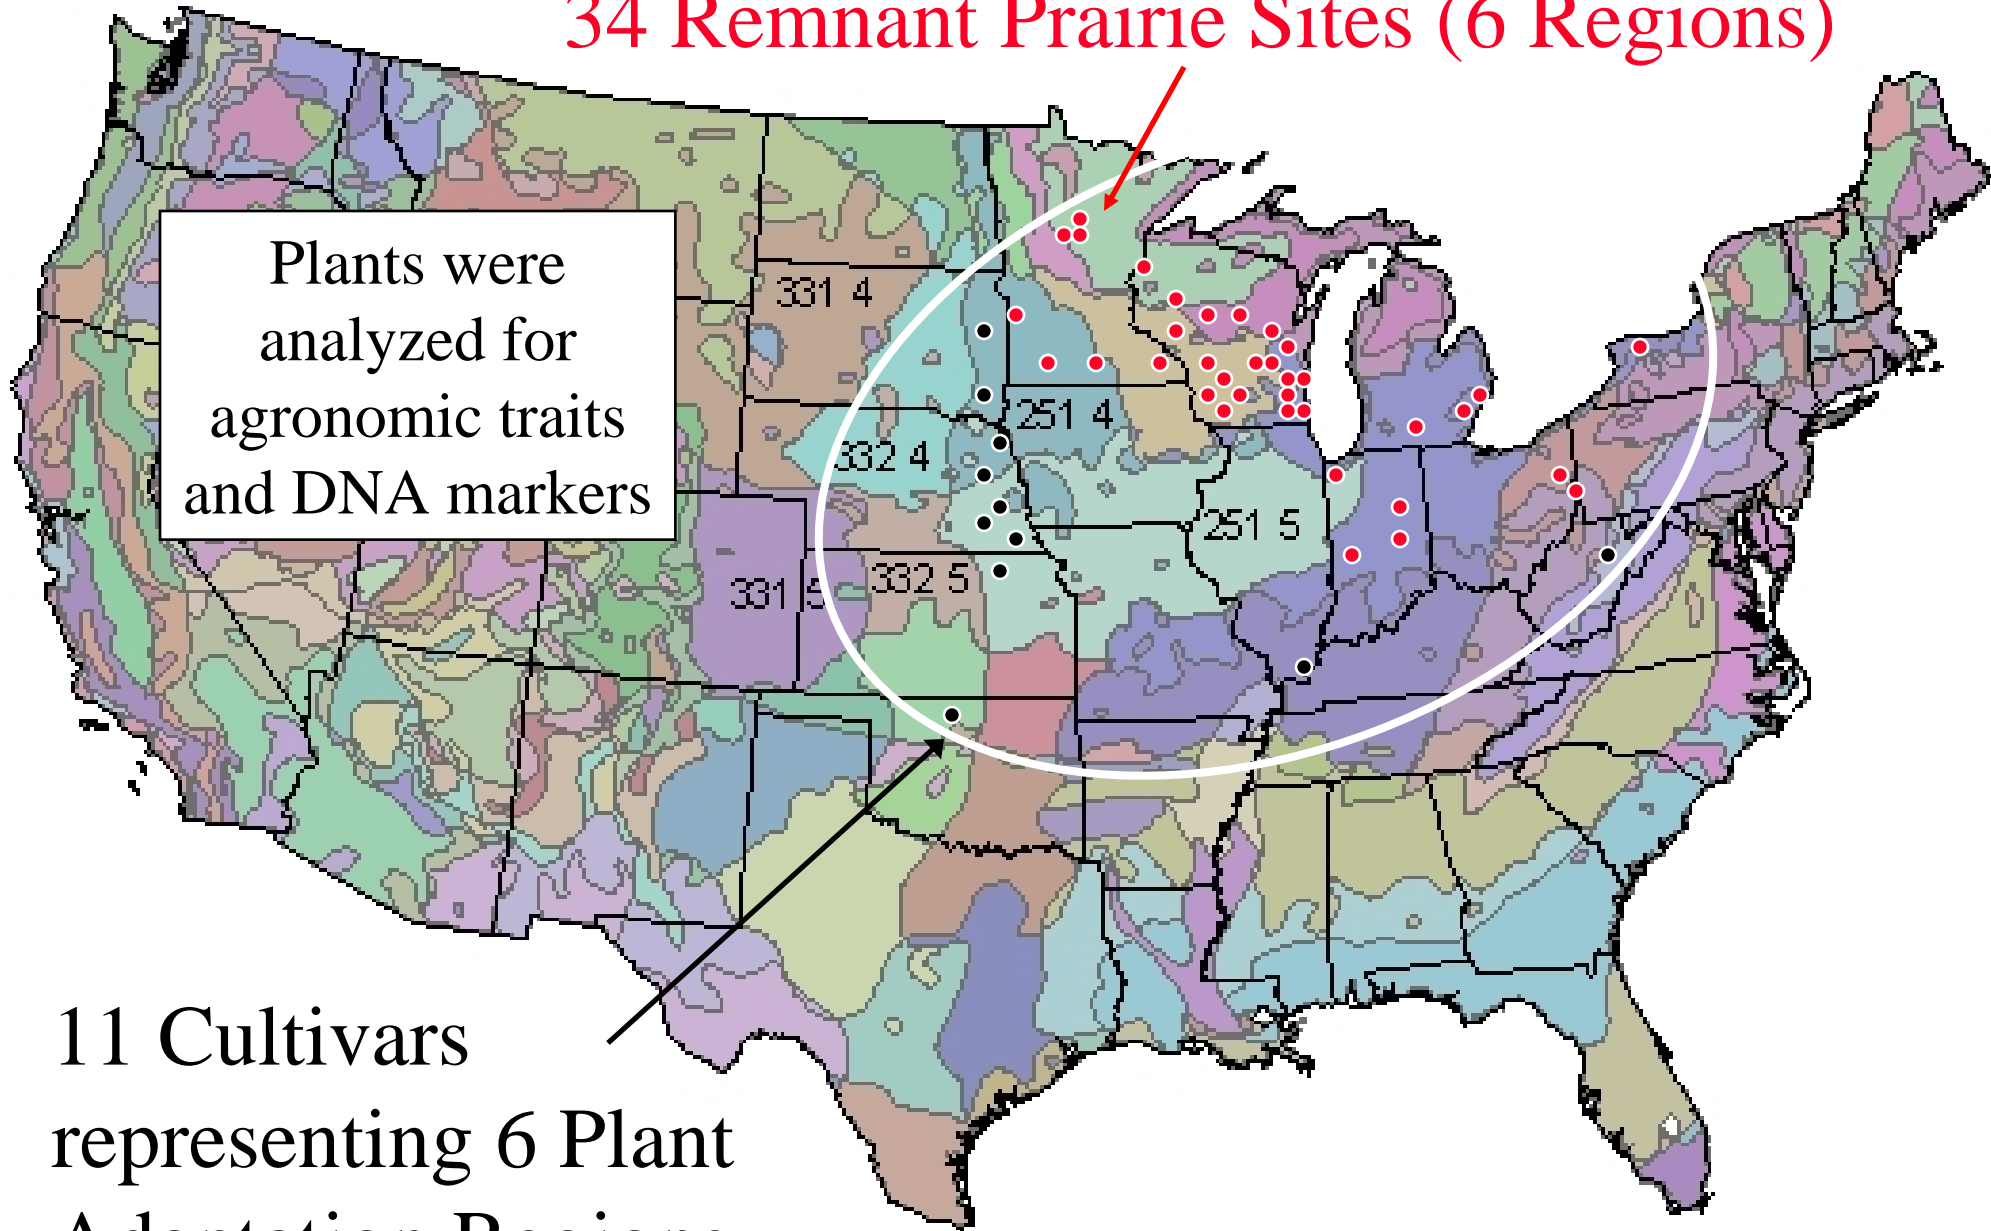

Biomass yield: Cytotypes & Origins

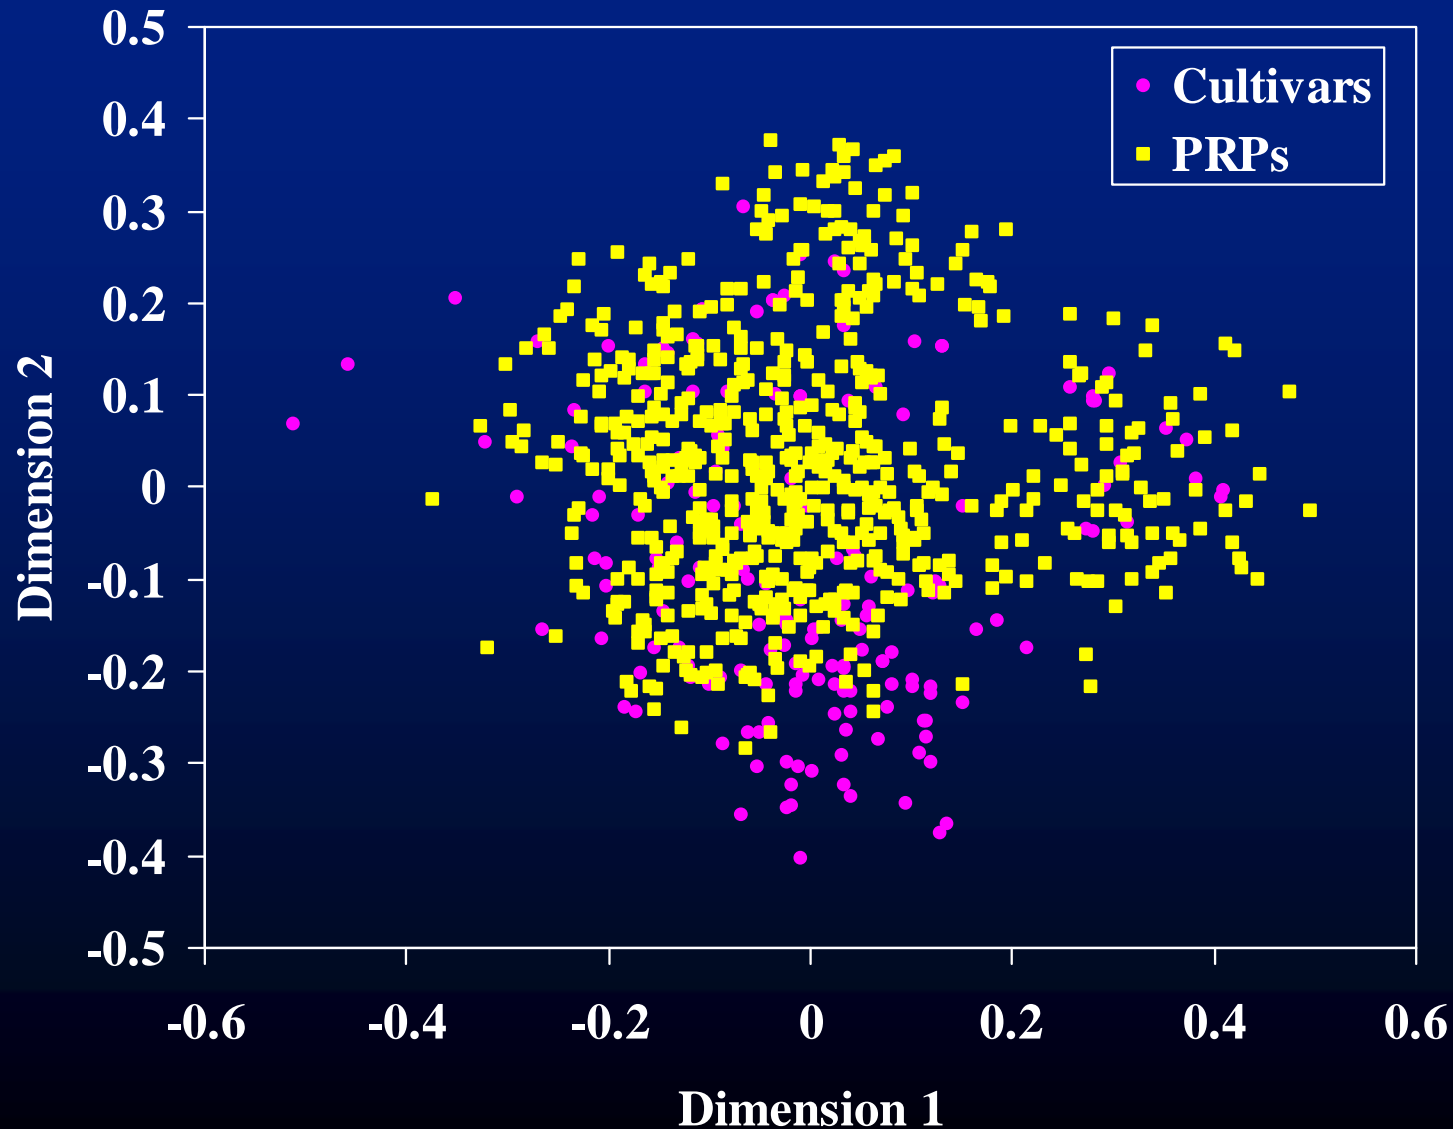

34 Remnant Prairie Sites (6 Regions)

Plants were
analyzed for
agronomic traits
and DNA markers

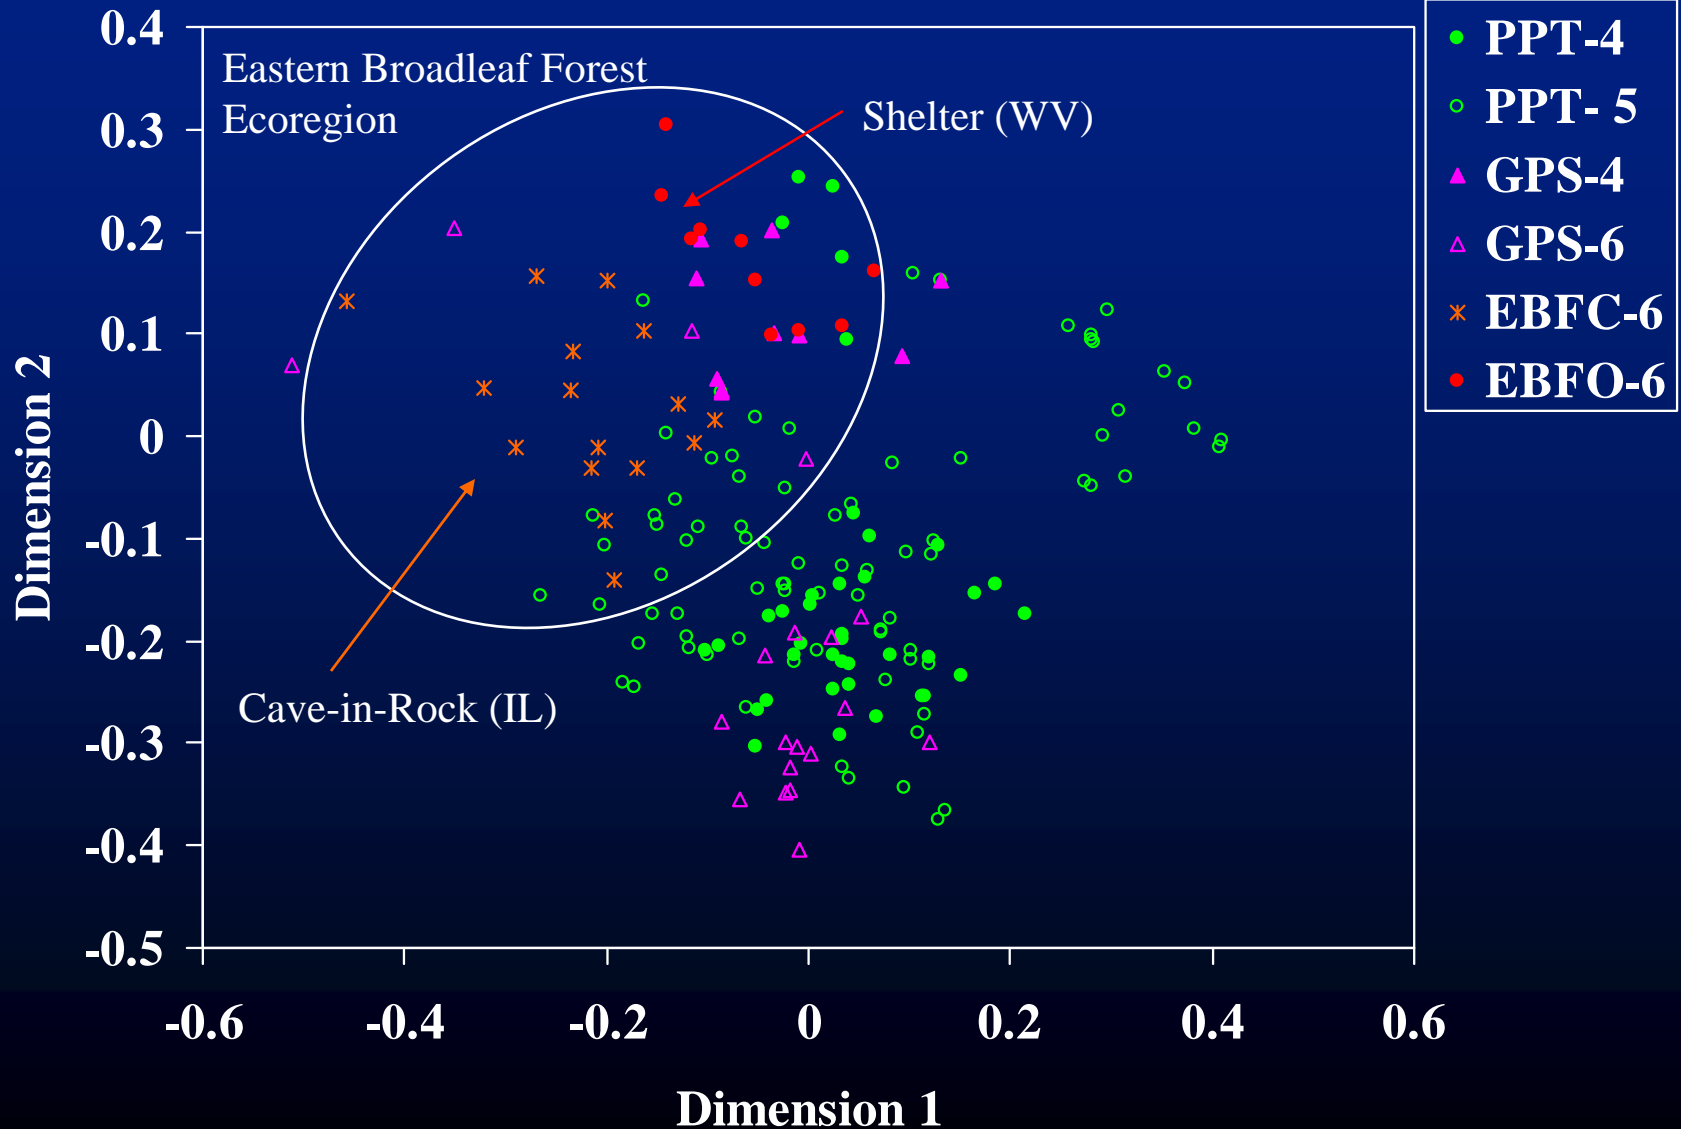

11 Cultivars
representing 6 Plant
Adaptation Regions

Cultivars vs. Prairie-Remnant Popns.

Switchgrass Cultivars

34 Prairie-Remnant Populations

34 Prairie-Remnant Populations

A map of the United States with a light green background. A large black arrow labeled "Prevailing Westerly Winds" points from the west towards the east. Three colored ovals represent air mass remnants: a red oval labeled "Dryland remnant" in the southwest, a blue oval labeled "Lowland Plains remnant" in the central region, and an orange oval labeled "Gulf Coast remnant" in the southeast. Arrows of corresponding colors point from these remnants towards the center. Two yellow double-headed arrows labeled "Mixing zones" are positioned between the Dryland and Lowland Plains remnants, and between the Lowland Plains and Gulf Coast remnants.

Switchgrass Gene Pools

- Individual populations of switchgrass, originating in remnant prairies, contain vast amounts of genetic diversity (~65-70% of the total variability).
- Individual populations do not contain unique genotypes or gene sequences, but share most of their gene sequences with other populations across a broad landscape.

Switchgrass Gene Pools

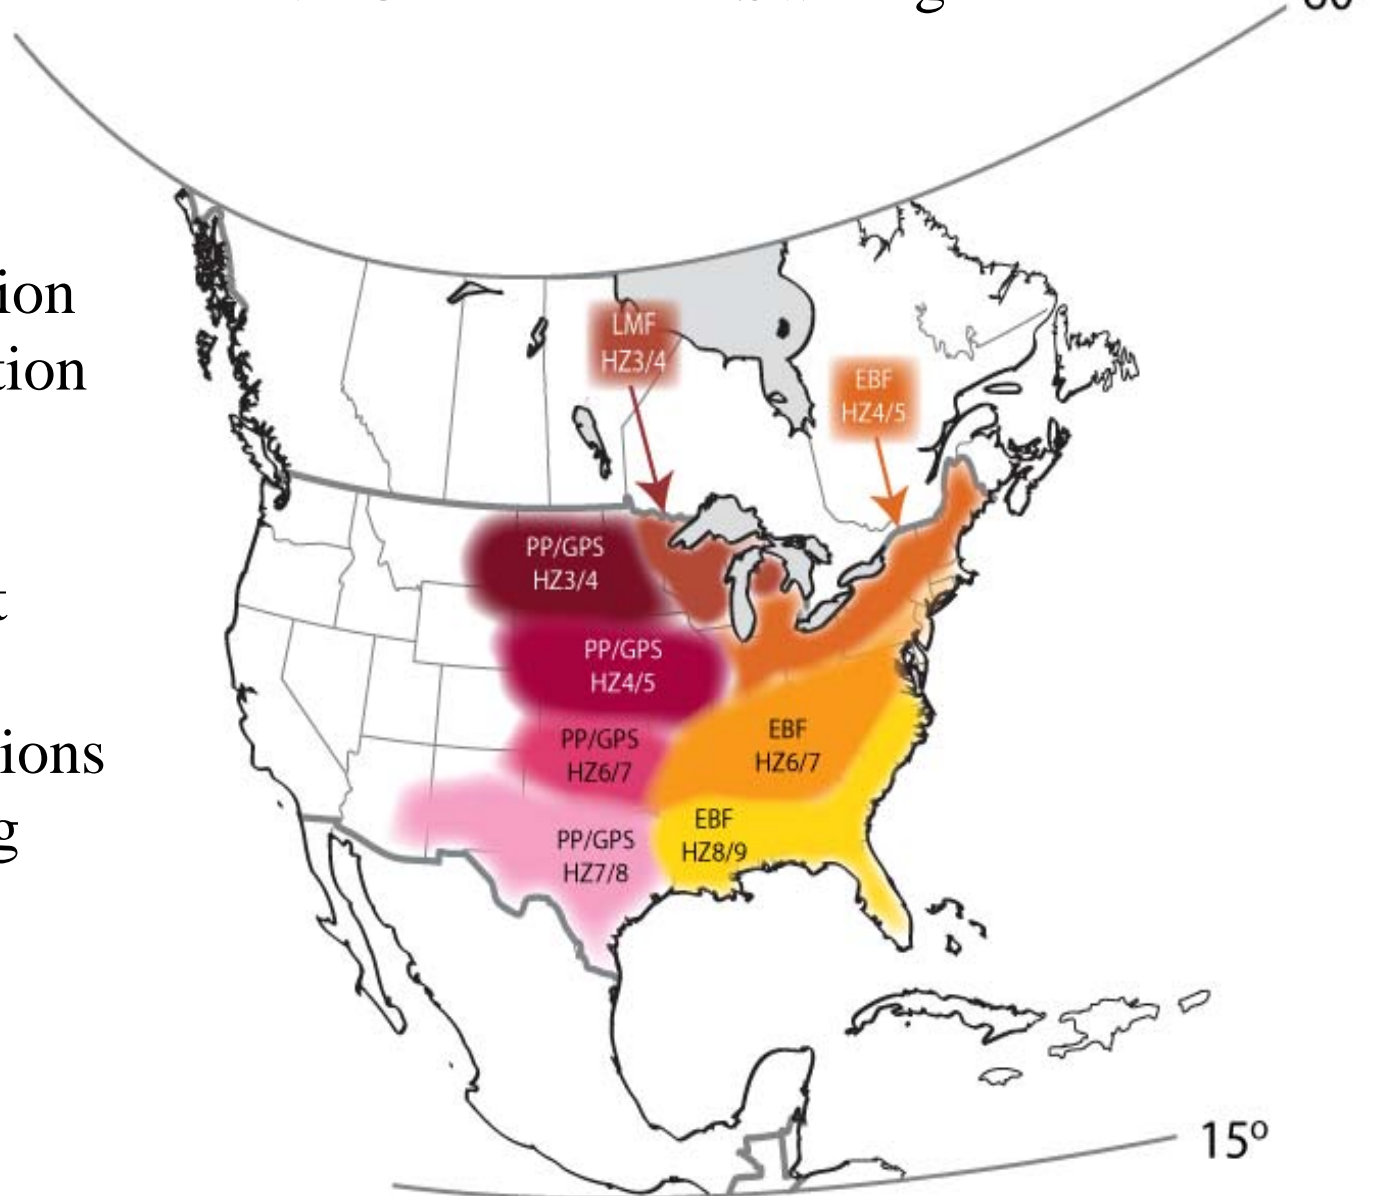

- Most population differentiation is based on phenotype, likely due to a very small number of genes that control adaptation traits.
- Northern populations tend to be earlier heading, higher in DM concentration, shorter, lower in biomass yield, higher in cold tolerance, and lower in heat tolerance.

Switchgrass Gene Pools

- Switchgrass gene pools can be functionally described based primarily on USDA Plant Hardiness Zones and secondarily on Bailey's Ecoregions.
- Germplasm originating within functional gene pools can be considered “free-ranging” within fairly large geographic regions defined by its phenotypic adaptation.

Effective Gene Pools of Switchgrass

- Conservation and restoration
- Cultivar deployment
- Target regions for breeding

Harvest Management

Vogel et al. (2002)

Nitrogen Fertilization

Vogel et al. (2002)

Energy Production in the Great Plains

On-farm Economic Analysis

- Field shown at right had a 5-yr average cost of \$30/U.S. ton switchgrass biomass including land costs.
- Average costs for 10 farms was \$49/ton; two experienced farmer's costs were \$36/ton.
- Each big bale (right) represents a 50 gallon barrel of ethanol at 80 gal/ton & farm gate cost of \$0.45/gallon.
- Bottom line – switchgrass economically feasible bioenergy crop.

Switchgrass field in NE South Dakota in 2005. Yields averaged 4 tons/acre (9 Mg/ha).

New “Biofeedstock” Cultivars

Cultivar	South	North	North
Blackwell	9.28	8.93	8.39
Cave-in-Rock	9.26	9.13	9.22
Pathfinder	8.12	8.51	8.39
Sunburst	8.31	9.20	10.44
St. Croix	9.30	9.40 (2%)	
Hiawatha	-	-	11.18 (7%)

Hybrid Vigor & Heterotic Groups

Group	Biomass yield (Mg/ha)
Lowland parent	7.1
Upland parent	6.1
Lowland x Lowland	7.3
Upland x Upland	6.2
Lowland x Upland	9.4 (32% heterosis)

Research Accomplishments

- Harvest management and timing
- Nitrogen fertilization rates
- Cultivar evaluations, classification, and geographic adaptation
- Genetic improvements and new cultivar development
- Genetic diversity and gene pools
- Production economics
